tem, auditory-evoked potentials elicit electro-physiological information up to the level of the brainstem (Elberling & Don, 1987; 2007). Stimulus Duration Another reason for discrepancies between the outcomes of the two measures of auditory thresholds is the duration of the stimuli. Pure tones used for behavioral audiometry are long-lasting compared to the brief tone bursts used for ABR.

In air, the auditory brainstem response audiogram showed a best sensitivity to sound of 300-500 Hz. Audiograms before and after removing the skin covering reveal that the cartilaginous tympanic disc shows unchanged sensitivity, indicating that the tympanic disc, and not the overlying skin, is the key sound receiver. If air and water thresholds are compared in terms of sound intensity
